Abstract

We revisit the Fritzsche-type lepton mass matrix models confronted with new experiments for neutrino mixings. It is shown that the model is viable and leads to a rather narrow range of free parameters. Using empirical mixing information between ν_e and ν_μ , and between ν_μ and ν_τ , it is predicted that the mixing angle between ν_e and ν_τ is in the range $0.04 < |U_{13}| < 0.20$, consistent with the CHOOZ experiment and the lightest neutrino mass is $0.0004 < m_1 < 0.0030$ eV. The range of the effective mass measured in double beta decay is $0.002 < \langle m_{ee} \rangle < 0.007$ eV.

During the last five years we have experienced dramatic advancement in empirical understanding of the mass and mixing of neutrinos. Most recently, the KamLAND experiment selected the neutrino mixing solution that is responsible for the solar neutrino problem nearly uniquely [1]: we are left with only so-called ‘large-mixing angle solution’ (LMA). We have now good understanding concerning the neutrino mass difference squared and mixing between ν_e and ν_μ [2], and between ν_μ and ν_τ [3]. An interesting constraint has also been placed on mixing between ν_e and ν_τ from the reactor experiment [4].

Anticipating that neutrinos are all massive from an early indication of the Kamiokande experiment [5], we proposed [6] that neutrino mass and mixing may be described by mass matrices similar to those proposed by Fritzsch for quarks [7]. After the secure confirmation of neutrino oscillation at SuperKamiokande [3], a large number of mass matrix models are proposed [8], but many of them among interesting models lead to bimaximal mixing. We now know that mixing between ν_e and ν_μ is large but not maximal [2], whereas mixing between ν_μ and ν_τ may be maximal [3]. This mixing pattern, together with small mixing between ν_e and ν_τ , is a characteristic embedded in the Fritzsch type matrices we proposed.

So, we revisit the Fritzsch-type mass matrix model to examine whether it is still consistent with all experiments. We find that it is, but the model leads, in particular after the KamLAND experiment, to a narrow allowed parameter range that can be tested in neutrino experiments we expect in the future.

A similar analysis was recently done by Xing [9]. The author, however, fixed the phases that appear in matrices to some arbitrary values. So his result is only a limited representation of the model. In this paper we have exhaustively studied for the allowed parameter space of the model.

The model we proposed in [6] consists of the mass matrices of the charged leptons and the Dirac neutrinos of the form

$$m_E = \begin{pmatrix} 0 & A_\ell & 0 \\ A_\ell & 0 & B_\ell \\ 0 & B_\ell & C_\ell \end{pmatrix}, \quad m_{\nu D} = \begin{pmatrix} 0 & A_\nu & 0 \\ A_\nu & 0 & B_\nu \\ 0 & B_\nu & C_\nu \end{pmatrix}, \quad (1)$$

where each entry is complex, and the right-handed Majorana mass matrix

$$M_R = M_0 \mathbf{I}, \quad (2)$$

where M_0 is a very large mass. We assume that neutrinos are of the Majorana type. We obtain small neutrino masses m_1 , m_2 and m_3 through the seesaw mechanism, as

$$m_i = m_{\nu D}^T M_R^{-1} m_{\nu D}. \quad (3)$$

The lepton mixing matrix is given by¹

$$U = U_\ell^\dagger Q U_\nu \quad (4)$$

where

$$\begin{aligned} U_\ell(1,1) &= \sqrt{\frac{m_{2e}m_{3e}(m_{3e}-m_{2e})}{(m_{2e}+m_{1e})(m_{3e}-m_{2e}+m_{1e})(m_{3e}-m_{1e})}} \\ U_\ell(1,2) &= -\sqrt{\frac{m_{1e}m_{3e}(m_{3e}+m_{1e})}{(m_{2e}+m_{1e})(m_{3e}-m_{2e}+m_{1e})(m_{3e}+m_{2e})}} \\ U_\ell(1,3) &= \sqrt{\frac{m_{1e}m_{2e}(m_{2e}-m_{1e})}{(m_{3e}-m_{1e})(m_{3e}-m_{2e}+m_{1e})(m_{3e}+m_{2e})}} \\ U_\ell(2,1) &= \sqrt{\frac{m_{1e}(m_{3e}-m_{2e})}{(m_{2e}+m_{1e})(m_{3e}-m_{1e})}} \\ U_\ell(2,2) &= \sqrt{\frac{m_{2e}(m_{3e}+m_{1e})}{(m_{2e}+m_{1e})(m_{3e}+m_{2e})}} \\ U_\ell(2,3) &= \sqrt{\frac{m_{3e}(m_{2e}-m_{1e})}{(m_{3e}+m_{2e})(m_{3e}-m_{1e})}} \\ U_\ell(3,1) &= -\sqrt{\frac{m_{1e}(m_{2e}-m_{1e})(m_{3e}+m_{1e})}{(m_{3e}-m_{1e})(m_{3e}-m_{2e}+m_{1e})(m_{2e}+m_{1e})}} \\ U_\ell(3,2) &= -\sqrt{\frac{m_{2e}(m_{2e}-m_{1e})(m_{3e}-m_{2e})}{(m_{3e}+m_{2e})(m_{3e}-m_{2e}+m_{1e})(m_{2e}+m_{1e})}} \\ U_\ell(3,3) &= \sqrt{\frac{m_{3e}(m_{3e}+m_{1e})(m_{3e}-m_{2e})}{(m_{3e}+m_{2e})(m_{3e}-m_{2e}+m_{1e})(m_{3e}-m_{1e})}} \end{aligned} \quad (5)$$

¹Note that in [6] the mixing matrix is defined by $U = U_\nu^\dagger Q U_\ell$ in analogy to that in the quark sector. So U_{ij} is replaced with U_{ji}^* , when the present paper is compared with [6].

$$\begin{aligned}
U_\nu(1,1) &= \sqrt{\frac{m_{2D}m_{3D}(m_{3D}-m_{2D})}{(m_{2D}+m_{1D})(m_{3D}-m_{2D}+m_{1D})(m_{3D}-m_{1D})}} \\
U_\nu(1,2) &= -\sqrt{\frac{m_{1D}m_{3D}(m_{3D}+m_{1D})}{(m_{2D}+m_{1D})(m_{3D}-m_{2D}+m_{1D})(m_{3D}+m_{2D})}} \\
U_\nu(1,3) &= \sqrt{\frac{m_{1D}m_{2D}(m_{2D}-m_{1D})}{(m_{3D}-m_{1D})(m_{3D}-m_{2D}+m_{1D})(m_{3D}+m_{2D})}} \\
U_\nu(2,1) &= \sqrt{\frac{m_{1D}(m_{3D}-m_{2D})}{(m_{2D}+m_{1D})(m_{3D}-m_{1D})}} \\
U_\nu(2,2) &= \sqrt{\frac{m_{2D}(m_{3D}+m_{1D})}{(m_{2D}+m_{1D})(m_{3D}+m_{2D})}} \\
U_\nu(2,3) &= \sqrt{\frac{m_{3D}(m_{2D}-m_{1D})}{(m_{3D}+m_{2D})(m_{3D}-m_{1D})}} \\
U_\nu(3,1) &= -\sqrt{\frac{m_{1D}(m_{2D}-m_{1D})(m_{3D}+m_{1D})}{(m_{3D}-m_{1D})(m_{3D}-m_{2D}+m_{1D})(m_{2D}+m_{1D})}} \\
U_\nu(3,2) &= -\sqrt{\frac{m_{2D}(m_{2D}-m_{1D})(m_{3D}-m_{2D})}{(m_{3D}+m_{2D})(m_{3D}-m_{2D}+m_{1D})(m_{2D}+m_{1D})}} \\
U_\nu(3,3) &= \sqrt{\frac{m_{3D}(m_{3D}+m_{1D})(m_{3D}-m_{2D})}{(m_{3D}+m_{2D})(m_{3D}-m_{2D}+m_{1D})(m_{3D}-m_{1D})}}
\end{aligned} \tag{6}$$

where 1-3 refers to generation; Q is a phase matrix written as

$$Q = \begin{pmatrix} 1 & 0 & 0 \\ 0 & e^{i\sigma} & 0 \\ 0 & 0 & e^{i\tau} \end{pmatrix}, \tag{7}$$

which is a reflection of phases contained in the charged lepton mass matrix and the Dirac mass matrix of neutrinos. The phases are neglected in the right-handed neutrinos mass matrix. In the presence of mass hierarchy of the left-handed neutrinos, the effect of phases in the right-handed mass matrix is small, and the inclusion of phases changes the analysis only little. Since the charged lepton masses are well-known, the number of parameters contained in our model is six: m_{1D} , m_{2D} , m_{3D} , σ , τ and M_0 . These parameters are to be determined by empirical neutrino mass and mixing.

We calculate lepton mixing matrix elements using the exact expressions, but they are written approximately

$$\begin{aligned}
U_{12} &\simeq -\left(\frac{m_1}{m_2}\right)^{1/4} + \left(\frac{m_e}{m_\mu}\right)^{1/2} e^{i\sigma} \\
U_{21} &\simeq \left(\frac{m_1}{m_2}\right)^{1/4} e^{i\sigma} - \left(\frac{m_e}{m_\mu}\right)^{1/2} \\
U_{23} &\simeq \left(\frac{m_2}{m_3}\right)^{1/4} e^{i\sigma} - \left(\frac{m_\mu}{m_\tau}\right)^{1/2} e^{i\tau} \\
U_{32} &\simeq -\left(\frac{m_2}{m_3}\right)^{1/4} e^{i\tau} + \left(\frac{m_\mu}{m_\tau}\right)^{1/2} e^{i\sigma} \\
U_{13} &\simeq \left(\frac{m_e}{m_\mu}\right)^{1/2} U_{23} + \left(\frac{m_2}{m_3}\right)^{1/2} \left(\frac{m_1}{m_3}\right)^{1/4} \\
U_{31} &\simeq \left(\frac{m_1}{m_2}\right)^{1/4} U_{32}
\end{aligned} \tag{8}$$

where $(m_e/m_\tau)^{1/2}$ is neglected. Rough characteristics of mixing angles are understood from these expressions.

For our analysis we take as inputs

$$\Delta m_{\text{atm}}^2 = (1.5 - 3.9) \times 10^{-3} \text{eV}^2, \quad \sin^2 \theta_{\text{atm}} \geq 0.92 \tag{9}$$

for $\nu_\mu - \nu_\tau$ mixing from Super-Kamiokande experiment [3], and

$$\Delta m_{\text{sol}}^2 = (6 - 8.5) \times 10^{-5} \text{eV}^2, \quad \sin^2 \theta_{\text{sol}} = 0.25 - 0.4 \tag{10}$$

for $\nu_e - \nu_\mu$ mixing from KamLAND [1], both at a 90% confidence level.

The KamLAND experiment gives another, but less favoured solution within LMA, i.e., the solution allowed only at a 95% confidence level,

$$\Delta m_{\text{sol}}^2 = (1.4 - 1.8) \times 10^{-4} \text{eV}^2, \quad \sin^2 \theta_{\text{sol}} = 0.27 - 0.34 \tag{11}$$

which we call KamLAND-B (we call the best favoured solution (10) KamLAND-A). For this case we take a region allowed at a 95% confidence for the Super-Kamiokande data for $\nu_\mu - \nu_\tau$ mixing for consistency.

We discuss how the allowed parameter region shrunked after the KamLAND data which determined the mass difference squared to a high accuracy. For a purpose of comparison, we also take the LMA for the $\nu_e - \nu_\mu$ mixing before the KamLAND data [2]:

$$\Delta m_{\text{sol}}^2 = (3 - 20) \times 10^{-5} \text{eV}^2, \quad \sin^2 \theta_{\text{sol}} = 0.23 - 0.41 \quad (12)$$

at a 90% confidence level.

We assume that $m_{3\nu} \gg m_{i\nu}$ for $i = 1, 2$, i.e., $\Delta m_{\text{atm}}^2 \simeq m_3^2$. We do not assume mass hierarchy between $m_{\nu 1}$ and $m_{\nu 2}$. We do *not* include the empirical constraint from the CHOOZ experiment for mixing between ν_e and ν_τ in our analysis. We leave this as a free parameter and examine the result against experiment.

We have exhaustively searched for allowed parameter regions that satisfy empirical mass difference squared and mixing in six dimensional space without any prior conditions.

The result is restrictive. We plot in Figure 1 m_1/m_3 as a function of $|U_{e3}|$ for KamLAND-A. The outer contour shows an allowed region before the KamLAND data are available. The model predicts $0.04 < |U_{e3}| < 0.18$. It is interesting to note that the model upper limit agrees with the empirical constraint from the CHOOZ experiment $|U_{e3}| < 0.16$ and that there is a definite lower limit on $|U_{e3}|$. The lightest neutrino mass m_1 cannot be too small. When m_2 is used as a unit, $m_1/m_2 = 0.05 - 0.29$ is the allowed range, or $m_1 = 0.0004 - 0.0030$ eV. Of course, $m_1 < m_2$ is always satisfied because θ_{solar} does not reach 45° .

A similar figure is presented for KamLAND-B solution at a 95% confidence level (Figure 2).

The allowed range of the lepton flavour mixing matrix (for KamLAND-A) is given as

$$|U| = \begin{bmatrix} 0.76 - 0.86 & 0.50 - 0.63 & 0.04 - 0.19 \\ 0.27 - 0.48 & 0.63 - 0.72 & 0.60 - 0.71 \\ 0.34 - 0.49 & 0.42 - 0.58 & 0.71 - 0.80 \end{bmatrix} . \quad (13)$$

This matrix may be compared with a model-independent analysis of neutrino mixing [10], which is modified very little even after the KamLAND experiment. We see general agreement between the two matrices, while the allowed ranges of each matrix element in the present model is quite narrow.

In Figure 3 (Figure 4 for KamLAND-B) we show the rephasing invariant CP violation measure J_{CP} [11], which is defined by

$$J_{CP} = \text{Im} [U_{\mu 3} U_{\tau 3}^* U_{\mu 2}^* U_{\tau 2}] . \quad (14)$$

as a function of $|U_{e3}|$.

Figures 5 and 6 present experimentally more relevant quantities, the CP violating part of neutrino oscillation

$$\begin{aligned} \Delta P &\equiv P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e) - P(\nu_\mu \rightarrow \nu_e) = P(\nu_\mu \rightarrow \nu_\tau) - P(\bar{\nu}_\mu \rightarrow \bar{\nu}_\tau) \\ &= P(\bar{\nu}_e \rightarrow \bar{\nu}_\tau) - P(\nu_e \rightarrow \nu_\tau) , \end{aligned} \quad (15)$$

and effective mass measured in double beta decay experiment $\langle m_{ee} \rangle$

$$\langle m_{ee} \rangle = m_1 U_{e1}^2 + m_2 U_{e1}^2 + m_3 U_{e3}^2 \quad (16)$$

for KamLAND-A case. Here, ΔP is given by

$$\Delta P = 4J_{CP}f_{CP} \quad (17)$$

where

$$f_{CP} \equiv -4 \sin \frac{\Delta m_{21}^2 L}{4E} \sin \frac{\Delta m_{32}^2 L}{4E} \sin \frac{\Delta m_{31}^2 L}{4E} , \quad (18)$$

with $\Delta m_{ij} = m_i^2 - m_j^2$ and ΔP is evaluated for $\langle E_\nu \rangle = 1.3\text{GeV}$ and $L = 295\text{Km}$, which are parameters for a planned long-baseline neutrino oscillation experiment between the Japanese Hadron Facility (JHF) in Tokai Village (Ibaraki) to the Super-Kamiokande.

Note that the figure of $\langle m_{ee} \rangle$ does not include the error of m_3 , but fixed at 0.053 eV. The result should be scaled if actual m_3 is higher or lower. The effective mass measured in the double beta decay ranges from 2 – 7 meV for $m_3 = 0.053$ (eV). The lower limit is raised by a factor of 4 after the KamLAND experiment.

Predictions are summarized in Table 1. We emphasize that interesting features of this model are mixing between ν_e and ν_μ that is not maximal, unlike in the model proposed in [12] based on the democratic principle or that in the Zee model [13,14], whereas $|U_{13}|$ is automatically predicted to be small (but non-zero) [8]. Basic features found in experiment seem to be built-in in this model. Without any knowledge for the right-handed neutrino sector, we assumed that the right-handed neutrino mass is proportional to a unit matrix. Modifications for the prediction on the mixing angles are relatively minor even if we somewhat relax this assumption, in so far as the mass hierarchy in the Dirac mass is not disturbed. In conclusion, a simple Fritzsch-type model we proposed in [6] is consistent with all existing neutrino experiments, but the model parameters are now restricted to a narrow range that endows the model with a predictive power.

	m_2/m_3 (input)	m_1/m_3	$ U_{e3} $	$ J_{CP} $	$\langle m_{ee} \rangle$ (meV)
KamLAND-A	$0.11 - 0.19$	$0.007 - 0.056$	$0.042 - 0.191$	≤ 0.021	$1.9 - 6.7$
KamLAND-B	$0.18 - 0.28$	$0.011 - 0.046$	$0.081 - 0.202$	≤ 0.025	$3.3 - 8.3$
Before KamLAND	$0.08 - 0.28$	$0.005 - 0.073$	$0.025 - 0.202$	≤ 0.025	$1.3 - 9.5$
